

In regression Equation (1), the dependent variable is urbanization in polity j at time t , while the explanatory variables are time and polity fixed effects, and the number of years of French presence in polity j interacted with the time effects. This regression corresponds to Regression 1. The stable groups assumption is satisfied as there are several polities that did not experience any year of French presence. This is a sharp design.

15. **Baum-Snow and Lutz (2011), School Desegregation, School Choice, and Changes in Residential Location Patterns by Race.** *Tables 2 to 6.*

In regression Equation (1), the dependent variable is, say, whites public school enrolment in MSA j in year t , while the explanatory variables are MSA and region $\times$ time fixed effects, and an indicator for whether MSA j is desegregated. This regression corresponds to Regression 1 with controls. The stable groups assumption is satisfied: between each pair of consecutive years, there are MSAs whose desegregation status does not change. This is a sharp design.

16. **Dinkelman (2011), The Effects of Rural Electrification on Employment: New Evidence from South Africa.** *Tables 4 and 5 Columns 5-8, Table 8 Columns 3-4, Table 9 Column 2, and Table 10 Columns 2, 4, and 6.*

In regression Equation (3), the dependent variable is, say, the first difference of the female employment rate for community j between periods 1 and 2, and the explanatory variables are district fixed effects, the change of electrification status of community j between periods 1 and 2, and some statistical controls. The land gradient in community j is used as an instrument for the change in electrification. This regression corresponds to the 2SLS version of Regression 2 with some controls. The stable groups assumption is presumably satisfied: it is likely that there are communities whose land gradient is 0. This is a sharp design.

17. **Enikolopov et al. (2011), Media and Political Persuasion: Evidence from Russia.** *Table 3.*

In regression Equation (5), the dependent variable is the share of votes for party j in election-year t and subregion s , and the explanatory variables are subregion and election fixed effects, and the share of people having access to NTV in subregion s in election-year t . This regression corresponds to Regression 1. The stable groups assumption is not satisfied: the share of people having access to NTV strictly increases in all regions between 1995 and 1999, the two elections used in the analysis. This a fuzzy design: the treatment of interest is whether a person has access to NTV, which varies within (subregion,year) cells.

18. **Fang and Gavazza (2011), Dynamic Inefficiencies in an Employment-Based Health Insurance System: Theory and Evidence.** *Tables 2, 3, 5, and 6, Column 3.*

In regression Equation (7), the dependent variable is the health expenditures of individual j working in industry i in period t and region r , and the explanatory variables are individual

effects, region specific time effects, and the job tenure of individual j . The death rate of establishments in industry i in period t and region r is used as an instrument for the job tenure of individual j . This regression is the 2SLS version of Regression 2 with controls. The stable groups assumption is presumably satisfied: between each pair of consecutive years, it is likely that there are some industry $\times$ region pairs where the death rate of establishments does not change. This a fuzzy design: the instrument of interest is whether a person's former employee closed down over the current year, which varies within (industry,year) cells.

19. **Gentzkow et al. (2011), The Effect of Newspaper Entry and Exit on Electoral Politics.** *Tables 2 and 3.*

In regression Equation (2), the dependent variable is the change in voter turnout in county c between elections year t and $t-1$, and the explanatory variables are state $\times$ year effects, and the change in the number of newspapers in county c between t and $t-1$. This regression corresponds to Regression 2 with controls. The stable groups assumption is satisfied: between each pair of consecutive years, there are some counties where the number of newspapers does not change. This is a sharp design.

20. **Bloom et al. (2012), Americans Do IT Better: US Multinationals and the Productivity Miracle.** *Table 2, Columns 6-8.*

In the regression in, say, Column 6 of Table 2, the dependent variable is the log of output per worker in firm i in period t , while the explanatory variables are firms and time fixed effects, the log of the amount of IT capital per employee $\ln(C/L)$, the interaction of $\ln(C/L)$ and an indicator for whether the firm is owned by a US multinational, the interaction of $\ln(C/L)$ and an indicator for whether the firm is owned by a non-US multinational, and some controls. This regression is similar to Regression 1 with some controls, except that it has three treatment variables. The stable groups assumption is presumably satisfied: between each pair of consecutive years, it is likely that there are some firms where the amount of IT capital per employee $\ln(C/L)$ does not change. This is a sharp design.

21. **Simcoe (2012), Standard Setting Committees: Consensus Governance for Shared Technology Platforms.** *Table 4, Columns 1-3.*

In regression Equation (5), the dependent variable is a measure of time to consensus for project i submitted to committee j , while the explanatory variables are an indicator for projects submitted to the standards track, a measure of distributional conflict, the interaction of the standards track and distributional conflict, and some controls variables. This regression is similar to Regression 1 with some controls, except that it has a measure of distributional conflict instead of committee fixed effects. The stable groups assumption is presumably not satisfied: it is unlikely that there is any committee where the measure of

distributional conflict is equal to 0. This is a sharp design.

22. **Moser and Voena (2012), Compulsory Licensing: Evidence from the Trading with the Enemy Act.** *Table 2.*

In the regression equation in the beginning of Section III, the dependent variable is the number of patents by US inventors in patent class c at period t , and the explanatory variables are patent class and time fixed effects, the interaction of period t being after the trading with the enemy act and the number of licensed patents in class c , and some control variables. This regression corresponds to Regression 1 with some controls. The stable groups assumption is satisfied: there are patent classes where no patent was licensed. This is a sharp design.

23. **Forman et al. (2012), The Internet and Local Wages: A Puzzle.** *Tables 2 and 4.*

In regression Equation (1), the dependent variable is the difference between log wages in 2000 and 1995 in county i , and the explanatory variables are the proportion of businesses using Internet in county i in 2000, and control variables. This regression corresponds to Regression 2 with some controls. The stable groups assumption is satisfied: there are counties with no Internet investment in 2000. This a fuzzy design: the treatment of interest is whether a business uses Internet, which varies within (county,year) cells.

24. **Besley and Mueller (2012), Estimating the Peace Dividend: The Impact of Violence on House Prices in Northern Ireland.** *Table 1, Columns 3 and 5-7.*

In regression Equation (1), the dependent variable is the price of houses in region r at time t , while the explanatory variables are region and time fixed effects, and the number of people killed because of the civil war in region r at time $t-1$. This regression corresponds to Regression 1. The stable groups assumption is presumably satisfied: between each pair of consecutive years, it is likely that there are some regions where the number of people killed because of the civil war does not change. This is a sharp design.

25. **Dafny et al. (2012), Paying a Premium on Your Premium? Consolidation in the US Health Insurance Industry.** *Table 3.*

In regression Equation (3), the dependent variable is the the concentration of the hospital industry in market m and year t , and explanatory variables are time fixed effects, market fixed effects, and the change in concentration in market m induced by a merger interacted with an indicator for t being after the merger. This regression corresponds to Regression 1. The stable groups assumption is satisfied: there are many markets where the merger did not change concentration. This is a sharp design.

26. **Hornbeck (2012), The Enduring Impact of the American Dust Bowl: Short- and Long-Run Adjustments to Environmental Catastrophe.** *Table 2.* In regression

Equation (1), the dependent variable is, say, the change in log land value in county c between period t and 1930, and the explanatory variables are state $\times$ year fixed effects, the share of county c in high erosion regions, the share of county c in medium erosion regions, and some control variables. This regression is similar to Regression 1 with controls, except that it has two treatment variables. The stable groups assumption is satisfied: many counties have 0% of their land situated in medium or high erosion regions. This a fuzzy design: the treatments of interest are whether a piece of land is in high or in medium erosion regions, which varies within (county,year) cells.

27. **Bajari et al. (2012), A Rational Expectations Approach to Hedonic Price Regressions with Time-Varying Unobserved Product Attributes: The Price of Pollution.** *Table 5.*

In, say, the first regression equation in the bottom of page 1915, the dependent variable is the change in the price of house j between sales 2 and 3, and the explanatory variables are the change in various pollutants in the area around house j between sales 2 and 3, and some controls. This regression is similar to Regression 2 with controls, except that it has several treatment variables. The stable groups assumption is presumably satisfied: it is likely that for each pair of consecutive sales, there are houses where the level of each pollutant does not change. This is a sharp design.

28. **Dahl and Lochner (2012), The Impact of Family Income on Child Achievement: Evidence from the Earned Income Tax Credit.** *Table 3.*

In regression Equation (4), the dependent variable is the change in test scores for child i between years a and $a-1$, while the explanatory variables are the change in the EITC income of her family and some controls, and the change in the expected EITC income of her family based on her family income in year $a-1$ is used to instrument for the actual change of her family's EITC income. This regression is a 2SLS version of Regression 2 with controls, except that it does not have years fixed effects. The stable groups assumption is presumably satisfied: it is likely that for each pair of consecutive years, there are children whose family's expected EITC income does not change. This is a sharp design.

29. **Imberman et al. (2012), Katrina's Children: Evidence on the Structure of Peer Effects from Hurricane Evacuees.** *Tables 3-6.*

In regression Equation (1), the dependent variable is the test score of student i in school j in grade g and year t , and the explanatory variables are school and grade $\times$ year fixed effects, the fraction of Katrina evacuee students received by school j in grade g and year t , and some controls. This regression is a three-way fixed effects version of Regression 1. The stable groups assumption is satisfied: there are schools that did not receive any Katrina evacuee. This a fuzzy design: the treatment of interest is the proportion of evacuees in
