

have a college degree.

Occupations with a high share of college graduates have declining employment overall, with muted differences between more-exposed and less-exposed occupations compared to our main results. In contrast, occupations with a low share of college graduates have rising overall employment, with the least AI-exposed occupations growing and the most exposed occupations declining in employment. Further, for lower college share occupations, the dispersion in employment outcomes is visible in higher age groups as well, with workers up to age 40 showing separation in employment trends by AI exposure. These findings suggest that deteriorating education outcomes cannot fully explain our main results. They also suggest that for non-college workers, experience may serve as less of a buffer to labor market disruption than for college workers.

Occupational Interest Rate Exposure While estimates with firm-time effects control for overall hiring trends within firms, another possibility is that even within firms occupations with high AI exposure have high interest rate exposure, leading to contraction in hiring. We use occupational interest rate exposure data from [Zens et al. \(2020\)](#) to test for the correlation between interest rate exposure and AI exposure. Figure [A22](#) in fact finds that AI exposure and interest rate exposure are negatively correlated overall, with occupations such as construction having high interest rate exposure and low AI exposure. Figures [A23](#) and [A24](#) repeat our analysis separately for occupations below and above the median in interest rate exposure. Both cases are consistent with our main results, suggesting that occupational differences in interest rate exposure do not drive our results.

Other Robustness Checks Figures [A25](#) and [A26](#) show results separately for men and women. The results are similar, suggesting that diverging prospects for men and women are not driving our findings. Figure [A27](#) shows that results are similar when we do not take a balanced sample of firms. Figure [A28](#) shows similar results when including part-time and temporary workers.²⁷

Comparison to CPS Data A useful benchmark for our findings is to compare them to estimates from the monthly Current Population Survey (CPS). In Online Appendix [C](#) we perform similar analyses in the CPS, finding high levels of noise consistent with small sample sizes in fine age-

²⁷Another possibility is that employment trends reflect Covid-19 stimulus checks distorting labor supply. However, these payments were income-conditioned, and AI-exposed occupations average higher incomes ([Kochhar, 2023](#)), making this channel unlikely in explaining our findings.
