

firm regardless of AI exposure. For workers aged 22-25, we find a 15 log-point decline in relative employment for the most AI-exposed quintiles compared to the least exposed quintile, a large and statistically significant effect. Estimates for other age groups are much smaller in magnitude and not statistically significant. These findings imply that the employment trends we observe are not driven by differential shocks to firms that employ a disproportionate share of AI-exposed young workers.

Fifth, the labor market adjustments are visible in employment more than in compensation. In contrast to our findings for employment, we find little difference in annual salary trends by age or exposure quintile, suggesting possible wage stickiness. If so, AI may have larger effects on employment than on wages, at least initially, or even that AI may boost wages for as many workers as it hurts.

Sixth, the above facts are largely consistent across sample constructions designed to address various alternative explanations for the core findings. Our results are not driven solely by computer occupations or by occupations susceptible to remote work and outsourcing. We also find that the AI exposure taxonomy did not meaningfully predict employment outcomes for young workers further back in time, before the widespread use of LLMs, including during the unemployment spike driven by the COVID-19 pandemic. The patterns we observe in the data appear most acutely starting in late 2022 and early 2023, around the time of rapid proliferation of generative AI tools.³ They hold for both occupations with a high share of college graduates and ones with a low college share, suggesting deteriorating education outcomes during COVID-19 do not drive our results. For non-college workers, we find evidence that experience may serve as less of a buffer to labor market disruption, as low college share occupations exhibit divergent employment outcomes by AI exposure up to age 40.

While we explore a variety of alternative explanations, we caution that the facts we document may in part be influenced by factors other than generative AI. Taken as a whole, our results are consistent with the hypothesis that generative AI has begun to affect entry-level employment. We intend to continue to track the data on an ongoing basis to assess whether these trends change in the future.

³In particular, OpenAI introduced ChatGPT in November 2022. It was reported to have over 100 million active users by January 2023 and 1.7 billion website visitors in October 2023 (DeVon, 2023).

as Eloundou et al. (2024); Felten et al. (2023); Gmyrek et al. (2023); Handa et al. (2025), and Tomlinson et al. (2025) adapted this approach for Generative AI, forming the basis for exposure metrics used in this analysis. While these studies identify potential disruption, our paper connects these exposure measures to actual employment changes.

Our work broadens insights from studies that find significant effects in more specific settings, such as on online freelance platforms (Hui et al., 2023; Demirci et al., 2025) or within individual firms (Brynjolfsson et al., 2025; Dillon et al., 2025).⁶ We measure labor market changes across occupations spanning the US economy.

In this sense our work complements a small but growing list of papers using economy-wide data to measure AI’s impact. Recent findings have been varied. Jiang et al. (2025) find AI exposure correlates with longer work hours in the U.S.⁷ Hampole et al. (2025) use job postings and LinkedIn profiles from Revelio labs from 2011 to 2023 to find limited employment impacts overall, with growing labor demand at firms offsetting relative declines in demand for exposed occupations. Chandar (2025b) uses data from the CPS to compare employment changes in more and less AI-exposed professions, finding little differential trend overall but noting difficulty with measuring changes for young workers given limited effective sample size.⁸ Johnston and Makridis (2025) find employment increases in state-industry pairs more exposed to AI using Quarterly Census of Employment and Wages (QCEW) data.⁹ These prior papers use data lacking either sufficient granularity or immediacy to reliably study employment changes by AI exposure and age (O’Brien, 2025).¹⁰ In contrast, this paper uses large-scale, close to real-time data to take a step towards resolving the ongoing debate on the employment effects of AI on young workers.

After we first publicly shared our results, work by Hosseini and Lichtinger (2025) and Klein Teeselink (2025) similarly found declines in AI-exposed entry-level employment using LinkedIn data from the

⁶See also Noy and Zhang (2023); Peng et al. (2023); Dell’Acqua et al. (2023).

⁷See also Acemoglu et al. (2022); Bonney et al. (2024); Bick et al. (2024); Hartley et al. (2025); Frank et al. (2025); Chen et al. (2025).

⁸See Dominski and Lee (2025); Gimbel et al. (2025); Eckhardt and Goldschlag (2025), which also use CPS data.

⁹Johnston and Makridis (2025) measure state-industry exposure by taking an average of Eloundou et al. (2024)’s occupational exposure weighted by state-industry employment. Industry-level labor market changes may be distinct from the occupation-level changes studied in this paper if firms make capital investments or become more productive in ways that increases overall labor demand (Hampole et al., 2025).

¹⁰As a comparison, the CPS surveyed between 44,000 and 51,000 employed individuals in total across all age groups in each month since 2021. Between 10,000 and 12,000 of these observations were in the outgoing rotation group and included earnings records. The data in our main analysis sample includes between 250,000 and 350,000 employed individuals in each month *just between the ages of 22 and 25*, all with earnings records.

US and UK. In contrast, the most recent version of Humlum and Vestergaard (2025) found minimal effects on entry-level earnings or hours worked in Denmark.¹¹

3 Data Description

3.1 Payroll Data

This study uses data from ADP, the largest payroll processing firm in America. The company provides payroll services for firms employing over 25 million workers in the US. We use this to track employment changes for workers in occupations measured as more or less exposed to artificial intelligence.

We make several restrictions for our main analysis sample. We include only workers with positive earnings, exclude part-time employees, and subset to people under age 70.¹²

The set of firms using payroll services changes over time as companies join or leave ADP’s platform. We maintain a consistent set of firms by keeping only companies that have employee earnings records for each month from January 2021 through September 2025.

ADP observes job titles for about 70% of workers in its system. We exclude workers without a recorded job title. There are over 7,000 standardized job titles, including “Search engineer optimization specialist,” “Enterprise content management manager,” and “Plant documentation control specialist.” The company’s internal research team maps each of these job titles to a 2010 Standard Occupational Classification (SOC) code, additionally using information such as the job description, industry, location, and other relevant data. We use these estimated SOC codes to merge our data to occupational AI exposure measures.

After these restrictions we have records on 3.5 and 5 million workers each month for our main analysis sample, though we consider robustness to alternative analyses such as allowing for firms to enter and leave the sample.

While the ADP data include millions of workers in each month, the distribution of firms using

¹¹An important direction for future work is to reconcile differences among these recent studies, assessing the extent they arise from differences in labor market institutions, measurement of AI adoption, statistical methodology, or other factors.

¹²While we observe the year of birth for each worker, for privacy reasons we do not observe the exact date of birth. We impute month of birth from the distribution of birth months in the United States using data from the Center for Disease Control and Prevention.
