

Figure 5. Event-Study and Difference-in-Differences Estimates of the Effect of No-Fault Divorce on Female Suicide: Replication of Stevenson and Wolfers (2006)

Notes: The figure plots event-study estimates from the two-way fixed effects model on page 276 and plotted in figure 1 of Stevenson and Wolfers (2006), along with the DD coefficient. The specification does not include other controls and does not weight by population. Standard errors are robust to heteroskedasticity.

Figure 6. Difference-in-Differences Decomposition for Unilateral Divorce and Female Suicide

Notes: Notes: The figure plots each 2x2 DD components from the decomposition theorem against their weight for the unilateral divorce analysis. The open circles are terms in which one timing group acts as the treatment group and the pre-1964 reform states act as the control group. The closed triangles are terms in which one timing group acts as the treatment group and the non-reform states act as the control group. The x's are the timing-only terms. The figure notes the average DD estimate and total weight on each type of comparison. The two-way fixed effects estimate, -3.08, equals the average of the y-axis values weighted by their x-axis value.

Figure 7. Weighted Common Trends in the Unilateral Divorce Analysis: The Treatment/Control Weights on Each Timing Group

Notes: The figure plots the weights that determine each timing group's role in the weighted common trends expression. These are shown in solid triangles and equal the difference between the total weight each treatment timing group receives in terms where it is the treatment group (w_k^T) and terms where it is the control group (w_k^C): $w_k^T - w_k^C$. The solid circles show the same weights but for versions of each estimator that exclude the untreated (or already-treated) units and, therefore, are identified only by treatment timing. The open squares plot each group's sample share.

**Figure 8. Testing for Balance in a Difference-in-Differences Model with Timing:
Reweighted Test versus Joint Test**

Joint Test by Group: $\chi^2_2(24) = 23.8$ (p-val = 0.47)
 Joint Test of Reweighted Differences: $\chi^2(2) = 11.1$ (p-val = 0.00)

A. 1960 Per-Capita Income

B. 1960 M/F Sex Ratio

Notes: The figure plots average per-capita income and male/female sex ratio in 1960 for each timing group in the unilateral divorce analysis (combining the non-reform and pre-1964 reform states into the group labeled “Pre-64 + NRS”). The horizontal lines equal the average of these variables using the weights from figure 6 ($w_k^T - w_k^C$). Note that the 1969 states get more weight as a control group, so they are part of the reweighted control mean. Each panel reports the F -statistic and p -value from a joint test of equality across the means, and the reweighted difference, standard error, and p -value from the re-weighted balance test. The top of the figure reports $\chi^2(df)$ test-statistics for both covariates estimated using seemingly unrelated regressions.
