Figure 1: Weight on $CATT_{e,\ell'}$ for $\ell' \neq -2$ in the Coefficient μ_{-2} from Regression (23)

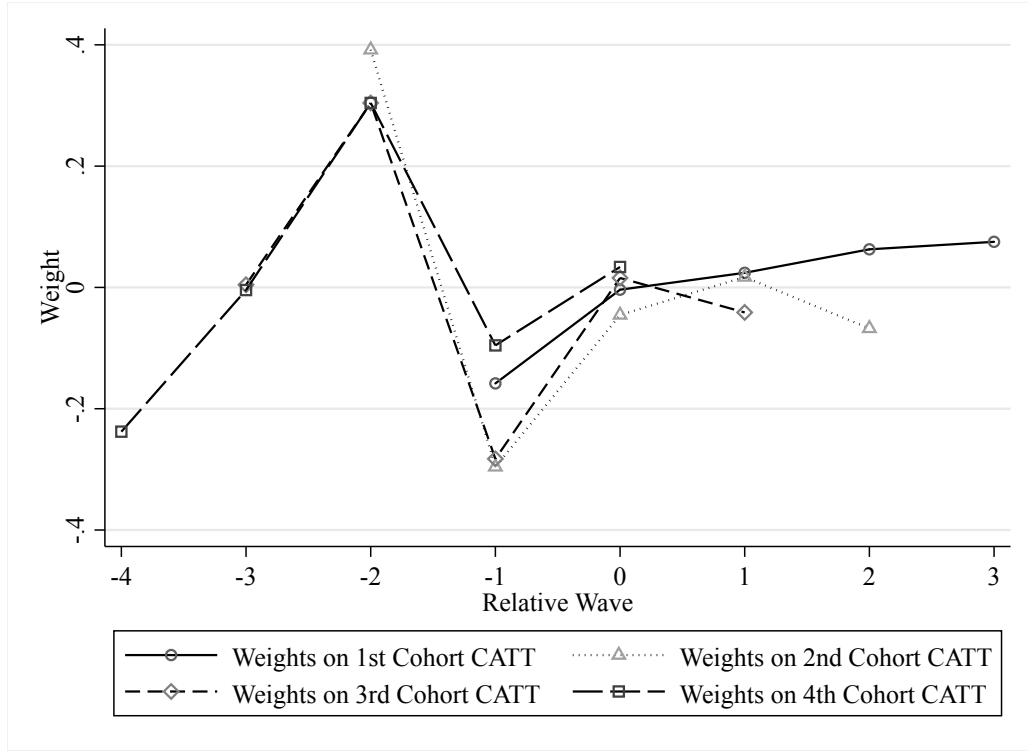

Notes: Panel (a) plots the weight on $CATT_{e,0}$ and panel (b) plots the weight on $CATT_{e,\ell'}$ for $\ell' \in \{-1, 1\}$ under a given distribution of cohorts indexed by the x -axis. Specifically, we construct a panel balanced in calendar time with $T = 2$ and cohorts $E_i \in \{1, 2, \infty\}$. We vary the share of never-treated units $Pr\{E_i = \infty\}$ between $[0, 0.99]$ and divide the rest of the units evenly into cohorts treated at time 1 and 2. The x -axis indexes $1 - Pr\{E_i = \infty\}$.

Figure 2: FE vs IW Estimates of the Effects of Hospitalization on Outcomes

Notes: Each figure plots FE estimates $\hat{\mu}_\ell$ from regression (29) in triangles and IW estimates $\hat{v}_\ell$ from regression (31) in circles against relative wave ℓ , with their respective pointwise 95% confidence intervals. Both are estimates for the effect of hospitalization at relative wave ℓ . The outcome variable is out-of-pocket medical spending in panel (a) and labor earnings in panel (b) respectively.

Figure 3: Estimated Weights $\widehat{\omega}_{e,\ell}^{-2}$ Underlying μ_{-2}

Notes: The FE estimator for the pretrend of hospitalization $\widehat{\mu}_{-2}$ estimates a linear combination of cohort-specific effects $CATT_{e,\ell}$'s from all cohorts e and relative waves ℓ as specified in equation (30). This figure plots the estimated weight $\widehat{\omega}_{e,\ell}^{-2}$ associated with each $CATT_{e,\ell}$ in this linear combination.
